Experiment No. 10
Implement program on Multithreading
Date of Performance:
Date of Submission:

**Aim:** Implement program on Multithreading

**Objective:**

**Theory:**

**Multithreading in Java** is a process of executing multiple threads simultaneously.

A thread is a lightweight sub-process, the smallest unit of processing. Multiprocessing and multithreading, both are used to achieve multitasking.

However, we use multithreading than multiprocessing because threads use a shared memory area. They don't allocate separate memory area so saves memory, and context-switching between the threads takes less time than process.

Java Multithreading is mostly used in games, animation, etc.

Java provides **Thread class** to achieve thread programming. Thread class provides constructors and methods to create and perform operations on a thread. Thread class extends Object class and implements Runnable interface.

There are two ways to create a thread:

1. By extending Thread class
2. By implementing Runnable interface.

**Thread class:**

Thread class provide constructors and methods to create and perform operations on a thread. Thread class extends Object class and implements Runnable interface.

### 1) Java Thread Example by extending Thread class

**FileName:** Multi.java

```
class Multi extends Thread{
    public void run(){
        System.out.println("thread is running...");
    }
    public static void main(String args[]){
        Multi t1=new Multi();
        t1.start();
    }
}
```

### Output:

thread is running...

### 2) Java Thread Example by implementing Runnable interface FileName: Multi3.java

```
class Multi3
implements
Runnable{ public
void run(){
System.out.println(
"thread is
running...");
}

public static
void main(String
args[]){Multi3
m1=new
Multi3();
Thread t1 =new Thread(m1); // Using the constructor
Thread(Runnable r)t1.start();
}
}
```

### Output:

thread is running...

### Code:

### Conclusion:

Comment on how multithreading is supported in JAVA.
